I PM Thomas last week for how [his estimated iterations](#) work.  
 Sadly, I still don't understand the geometric intuition ...

I know that is difficult to gauge whether a question is of general interest, but such explanations may help many (also those future readers!) and not only you, so if I were you I would ask in the public thread rather than in PM.

Wikis are great, [Contribute](#) :)

Maybe this video can give some geometric intuition:

Awesome Video Thomas, thanks for recommending it and the link! I certainly never learned Eigenvectors and Eigenvalues from this perspective, and it provides MUCH clarity for the mechanics underlying the number-crunching techniques I was taught. Having a better "feel" of what's going on, as this video provides, gives one much better insight into how to resolve issues when the 'normal equations/tools' don't work.

I will also check out some other videos in the same series. I'm always eager to learn stuff that's well presented, even if it is re-learning stuff I already supposedly know.

Thanks, I'll check these out as well.

After the original above, I stumbled onto [this video](#), with the first explanation of Euler's Identity I can honestly say I understood. So, while it now has a tiny bit less magic, it's still beautiful, and I can say I understand it.

**RE: [VA] SRC#003- New Year 2019 Special**Tried doing  $\sqrt{3}$  with this matrix power method, noticed a pattern:let  $M = \begin{Bmatrix} 1 & 3 \\ 1 & 1 \end{Bmatrix}$  $M^2 = \begin{Bmatrix} 3*1+1 & 3*(1+1) \\ 1+1 & 3*1+1 \end{Bmatrix} = \begin{Bmatrix} 4 & 6 \\ 2 & 4 \end{Bmatrix}$  $M^3 = \begin{Bmatrix} 3*2+4 & 3*(2+4) \\ 2+4 & 3*2+4 \end{Bmatrix} = \begin{Bmatrix} 10 & 18 \\ 6 & 10 \end{Bmatrix}$ 

Right diagonal ratio stayed at 3.0, and left diagonal same numbers.

-&gt; only need to do bottom row. Top row can be deduced if needed.

-&gt; each matrix multiply required only 2 add, and 1 multiply 😊

row 2 of  $M^4 = \{6+10, 3*6+10\} = \{16, 28\}$ row 2 of  $M^5 = \{16+28, 3*16+28\} = \{44, 76\}$ row 2 of  $M^6 = \{44+76, 3*44+76\} = \{120, 208\} \dots$

Doing the average of ratios, for  $M^6$ :  $\sqrt{3} \sim \frac{1}{2}(208/120 + 360/208) \sim \frac{1}{2}(1.733333 + 1.730769) = 1.732051$

Tried doing  $\sqrt{3}$  with this matrix power method, noticed a pattern:

let  $M = \{\{1,3\}, \{1, 1\}\}$

$M^2 = \{\{3*1+1, 3*(1+1)\}, \{1+1, 3*1+1\}\} = \{\{4,6\}, \{2,4\}\}$

$M^3 = \{\{3*2+4, 3*(2+4)\}, \{2+4, 3*2+4\}\} = \{\{10,18\}, \{6,10\}\} \dots$

To prove that the ratio converge to  $\sqrt{3}$ , noticed above actually does Farey Fraction:

$M^1$ :  $\sqrt{3}$  between  $1/1$  and  $3/1$ , so  $(1+3)/(1+1) = 4/2$  is better estimate.

$M^2$ :  $\sqrt{3}$  between  $4/2$  and  $3/(4/2) = 6/4$ , so  $(4+6)/(2+4) = 10/6$  is better estimate

$M^3$ : ...

Newton's method, does the same thing, but converge faster:  $x = \frac{1}{2}(x + 3/x)$

1:  $\frac{1}{2}(1/1 + 3*1/1) = 2/1 = 2$

2:  $\frac{1}{2}(2/1 + 3*1/2) = 7/4 = 1.75$

3:  $\frac{1}{2}(7/4 + 3*4/7) = 97/56 \sim 1.732143$

4:  $\frac{1}{2}(97/56 + 3*56/97) = 18817/10864 \sim 1.73205081$

The fractions are so good that all above (and at least 6 more !) are  $\sqrt{3}$  continued fraction convergents.

**RE: [VA] SRC#003- New Year 2019 Special**

The idea of only doing only \*last\* row work for 3x3 matrix too. 😊

Let  $M = \{\{k, n, n\}, \{1, k, n\}, \{1, 1, k\}\}$

->  $M^p = \{\{c, n*a, n*b\},$   
 $\{b, c, n*a\},$   
 $\{a, b, c\}\},$  for some  $a, b, c$

-> For  $M^{(p+1)}$ , **last row =  $\{k*a+b+c, n*a+k*b+c, n*a+n*b+k*c\}$**

Example: this is result of  $M^{200}$  last row ratios:

**Code:**

```
lua> k, n = math.pi, 2019
lua> a, b, c = 1, 1, k
lua> for i=2,200 do
```

```

:      a, b, c = (k*a+b+c)/n, a+(k*b+c)/n, a+b+k*c/n
:      end
lua> =a, b, c
2.916424658351884e-212  3.686063969271537e-211  4.658809733574611e-210
lua> =b/a, c/b
12.638982319380704      12.638982319385288

```
